Ultrasonography

Imaging devices using ultrasound in all Al-Hayat Medical centers service a lot of members. Ultrasound is sound waves reflected high frequency by body tissues at different angles to produce two-dimensional images typically on screen. This method is always used to monitor the fetus in pregnant women. Some other important uses are the imaging of the abdomen, heart, male genitalia, female pelvis, and veins. Ultrasound is considered one of the best diagnostic tools in many cases, especially cases that involve the study of physiological animation in real time. It's safe to use this method because the patient is not exposed to any radiation which can cause health problems. This method save a lot of time and effort to the patient.
